COMPLETE AI PROJECT GUIDE

Complex Engineering Problem (CEP) with Week-by-Week Solutions

SAMPLE CEP PROJECT

AI-Powered Smart City Traffic Management
Using Genetic Algorithms, A Search & Machine Learning*

Field	Details
Course	CSE-3636: Artificial Intelligence Lab
Instructor	Muhammad Mubinur Rahman
Institution	International Islamic University Chittagong
Department	Computer Science & Engineering
Academic Session	2024-2025
Project Type	Complex Engineering Problem (CEP)

1. Course Overview & Complex Engineering Attributes

This document provides a comprehensive example of a Complex Engineering Problem (CEP) project for CSE-3636: Artificial Intelligence Laboratory. The project is designed to satisfy three mandatory Complex Engineering Problem attributes (WP1, WP3, WP4) as defined by the Washington Accord. Every student group will be assigned a unique but equivalent CEP problem following the same structure.

Complex Engineering Problem (CEP) Attributes Required

Attribute	Code	Description	Coverage in This Project
Depth of Knowledge	WP1	Requires advanced AI/math knowledge — Genetic Algorithms, A* Search, heuristic design, graph theory, evolutionary computation	GA route optimization, A* pathfinding, heuristic functions, fitness landscape analysis
Depth of Analysis	WP3	No obvious solution; requires abstract thinking, competitive-programming-style Python problems	Multi-objective traffic optimization, NP-hard routing problems, dynamic constraint satisfaction
Familiarity of Issues	WP4	Infrequent or emerging research challenges, novel AI applications, original problem framing	Smart city AI applied to IIUC campus or Chittagong city, novel hybrid GA+A* pipeline

2. Sample CEP Project: AI-Powered Smart City Traffic Management

2.1 Problem Statement

Urban traffic congestion is an emerging and critical challenge in cities like Chittagong, Bangladesh. Traditional signal systems are static and fail to adapt to dynamic traffic patterns, causing significant economic and environmental damage. The problem of optimal real-time traffic signal scheduling across a city-wide road network is NP-hard and has no closed-form solution.

This project requires you to design, implement, and evaluate an AI system that uses Genetic Algorithms (GA) for global traffic schedule optimization and A* Search for real-time vehicle pathfinding — a novel hybrid approach with no established prior solution for the specific Chittagong road topology.

Why This is a Complex Engineering Problem

WP1 — Requires mastery of evolutionary computation mathematics (fitness functions, crossover operators, selection pressure), A* heuristics, graph representations, and optimization theory — all graduate-level concepts applied in combination.

WP3 — The multi-objective optimization (minimize travel time + maximize throughput + minimize emissions) has no polynomial-time exact solution. Students must devise novel fitness encodings and abstraction strategies.

WP4 — Applying hybrid evolutionary-search AI to real Bangladeshi urban road networks is an original contribution; no published benchmark exists for Chittagong city topology.

2.2 System Architecture

The system consists of four interconnected modules:

- Traffic Network Graph Builder — Converts road maps into weighted, directed graphs
- Genetic Algorithm Engine — Globally optimizes signal timing schedules across all intersections
- A* Pathfinding Engine — Provides real-time optimal routing for individual vehicles
- Performance Evaluation Module — Benchmarks GA, A*, BFS, DFS, Dijkstra, and Random Search

2.3 Learning Outcomes Covered

#	Learning Outcome	How Achieved
1	Graph search algorithms (A*, BFS, DFS, Dijkstra)	All implemented and compared on the traffic network
2	Evolutionary/genetic computation	Full GA with crossover, mutation, selection, and elitism
3	ML model integration	Decision Tree / Random Forest for traffic pattern prediction
4	Algorithm complexity analysis	Big-O analysis of each algorithm, empirical runtime plots
5	Dataset collection & preprocessing	Real/synthetic Chittagong traffic data pipeline
6	Multi-model comparison	6+ algorithms benchmarked on identical datasets
7	Novel contribution	Hybrid GA+A* pipeline is an original engineering contribution

3. Week-by-Week Work Plan with Complete Task Solutions

Each week has a defined deliverable that is graded. The instructor solution is provided below each task description for reference. Student groups will receive their own unique variant of each weekly task.

WEEK 1 WP4 — **Proposal Quality & Literature Review**

Task 1 — Project Proposal & Literature Review

Write a 2,000-word project proposal that: (1) defines the traffic optimization problem formally, (2) reviews at least 8 relevant papers on GA-based traffic control and A* pathfinding, (3) identifies the research gap, and (4) states measurable objectives.

Instructor Solution Outline — Week 1

Problem Formulation: Define G = (V, E, W) where V = intersections, E = road segments, W(e,t) = time-varying travel time. Objective: minimize total vehicle delay D = sum of (actual_travel_time - free_flow_time) across all vehicles.

Key Papers to Reference:

- Webster (1958) — Classic fixed-time signal optimization (baseline)
- Holland (1975) — Genetic Algorithms: foundations and convergence proofs
- Hart, Nilsson & Raphael (1968) — A* algorithm original paper, admissibility proof
- Srinivas & Patnaik (1994) — Adaptive probabilities in genetic algorithms
- Rojas-Morales et al. (2020) — ML-based dynamic traffic signal control
- Abdoos et al. (2011) — Multi-agent traffic signal control using RL
- Chiu & Chand (1993) — GA applied to traffic signal timing optimization
- Arel et al. (2010) — Deep RL for traffic light control (gap identified here)

Research Gap: No prior work applies a hybrid GA+A system to Bangladeshi road networks with real traffic density data. Novel contribution justified.*

WEEK 2 WP1 — **Dataset Preparation**

Task 2 — Traffic Network Dataset Construction

Construct a graph dataset representing a road network. Option A: Use OpenStreetMap data for Chittagong city (extracted via OSMnx). Option B: Construct a synthetic 20-node graph mimicking

real road topology. Each edge must have distance (km), speed limit, and a simulated time-varying congestion index.

Instructor Solution — Week 2 (Python Code)

Complete dataset construction script:

```
# Week 2: Dataset Preparation
# File: dataset_builder.py

import numpy as np
import pandas as pd
import networkx as nx
import random
import json

class TrafficNetworkDataset:
    def __init__(self, n_nodes=20, seed=42):
        random.seed(seed)
        np.random.seed(seed)
        self.n_nodes = n_nodes
        self.graph = nx.DiGraph()
        self.node_labels = {}   # node_id -> intersection name
        self.time_slots = 24    # hourly data for 24 hours

    def build_synthetic_chittagong_network(self):
        # Define intersection zones (simulating Chittagong areas)
        zones = ['GEC', 'Agrabad', 'Khulshi', 'Nasirabad',
                 'Patenga', 'IIUC', 'Muradpur', 'Dampara',
                 '2No Gate', 'Chawkbazar', 'Bahaddarhat',
                 'Oxygen', 'Sholoshahar', 'Pahartali', 'Halishahar',
                 'Kattali', 'Port Area', 'Tigerpass', 'Laldighi', 'Station']
        for i, name in enumerate(zones):
            lat = 22.30 + random.uniform(-0.15, 0.15)
            lon = 91.82 + random.uniform(-0.1, 0.1)
            self.graph.add_node(i, name=name, lat=lat, lon=lon)
            self.node_labels[i] = name

        # Add edges with realistic attributes
        edge_list = [
            (0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),
            (8,9),(9,10),(10,11),(11,12),(12,13),(13,14),(14,15),
            (15,16),(16,17),(17,18),(18,19),(19,0),

            (1,7),(7,13),(13,19),(19,1),(3,9),(9,15),
        ]
        for (u, v) in edge_list:
            dist = round(random.uniform(0.5, 8.0), 2)  # km
            speed = random.choice([30, 40, 50, 60])    # km/h
            self.graph.add_edge(u, v,
                distance=dist,
                speed_limit=speed,
                base_time=round((dist/speed)*60, 2),   # minutes
```

```
                road_type=random.choice(['arterial','collector','highway'])
            )
            # Add reverse direction
            self.graph.add_edge(v, u,
                distance=dist,
                speed_limit=speed,
                base_time=round((dist/speed)*60, 2),
                road_type=self.graph[u][v]['road_type']
            )
        return self.graph

    def generate_congestion_data(self):
        # Generate 30-day x 24-hour congestion index per edge
        n_days = 30
        records = []
        for day in range(n_days):
            for hour in range(24):
                # Rush hours: 8-9 AM and 5-7 PM
                rush = 1.0 + 1.5*np.exp(-((hour-8.5)**2)/2)
                rush += 1.2*np.exp(-((hour-17.5)**2)/2)
                for u, v, data in self.graph.edges(data=True):
                    noise = random.uniform(0.85, 1.15)
                    congestion = min(rush * noise, 3.5)
                    actual_time = data['base_time'] * congestion
                    records.append({
                        'day': day, 'hour': hour,
                        'from': u, 'to': v,
                        'congestion_index': round(congestion, 3),
                        'actual_travel_time': round(actual_time, 2),
                        'road_type': data['road_type']
                    })
        df = pd.DataFrame(records)
        df.to_csv('traffic_dataset.csv', index=False)
        print(f'Dataset saved: {len(df)} records')
        return df

# Run
if __name__ == '__main__':
    dataset = TrafficNetworkDataset(n_nodes=20)
    G = dataset.build_synthetic_chittagong_network()
    df = dataset.generate_congestion_data()
    print(f'Graph: {G.number_of_nodes()} nodes, {G.number_of_edges()} edges')
    print(df.head())
```

WEEK 3 WP1	Pre-processing Dataset

Task 3 — Data Cleaning, Feature Engineering & Normalization

Pre-process the traffic dataset: handle missing values, detect and remove outliers using Z-score, engineer time-based features (is_rush_hour, day_type), normalize features using Min-Max scaling, and split into 70/15/15 train/validation/test sets. Justify all preprocessing decisions.

Instructor Solution — Week 3 (Python Code)

```python
# Week 3: Pre-processing Pipeline
# File: preprocessing.py

import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.model_selection import train_test_split

class TrafficPreprocessor:
    def __init__(self, filepath='traffic_dataset.csv'):
        self.df = pd.read_csv(filepath)
        self.scaler = MinMaxScaler()

    def handle_missing(self):
        print(f'Missing before: {self.df.isnull().sum().sum()}')
        # Forward-fill time-series missing values
        self.df.fillna(method='ffill', inplace=True)
        self.df.fillna(method='bfill', inplace=True)
        print(f'Missing after: {self.df.isnull().sum().sum()}')

    def remove_outliers(self, col='congestion_index', threshold=3.0):
        z = np.abs((self.df[col] - self.df[col].mean()) / self.df[col].std())
        n_before = len(self.df)
        self.df = self.df[z < threshold]
        print(f'Outliers removed: {n_before - len(self.df)}')

    def feature_engineering(self):
        # Rush hour flag
        self.df['is_rush_hour'] = self.df['hour'].apply(
            lambda h: 1 if (7 <= h <= 9) or (16 <= h <= 19) else 0
        )
        # Day type (weekday: Mon=0..Fri=4, weekend: Sat=5,Sun=6)
        self.df['day_of_week'] = self.df['day'] % 7
        self.df['is_weekend'] = (self.df['day_of_week'] >= 5).astype(int)
        # Cyclical encoding of hour (preserves periodicity)
        self.df['hour_sin'] = np.sin(2 * np.pi * self.df['hour'] / 24)
        self.df['hour_cos'] = np.cos(2 * np.pi * self.df['hour'] / 24)
        print('Features engineered: is_rush_hour, is_weekend, hour_sin, hour_cos')

    def normalize(self):
        num_cols = ['congestion_index','actual_travel_time','hour_sin','hour_cos']
        self.df[num_cols] = self.scaler.fit_transform(self.df[num_cols])
        print('Normalization applied (MinMax)')

    def split(self):
        X = self.df.drop(columns=['actual_travel_time'])
        y = self.df['actual_travel_time']
        X_tr, X_tmp, y_tr, y_tmp = train_test_split(
            X, y, test_size=0.30, random_state=42)
```

```
        X_val, X_te, y_val, y_te = train_test_split(
            X_tmp, y_tmp, test_size=0.50, random_state=42)
        print(f'Train: {len(X_tr)}, Val: {len(X_val)}, Test: {len(X_te)}')
        return X_tr, X_val, X_te, y_tr, y_val, y_te

    def run(self):
        self.handle_missing()
        self.remove_outliers()
        self.feature_engineering()
        self.normalize()
        return self.split()

if __name__ == '__main__':
    prep = TrafficPreprocessor()
    X_tr, X_val, X_te, y_tr, y_val, y_te = prep.run()
```

WEEK 4
WP1 + WP3

Using a Sample ML/AI Model — A* Search

Task 4 — Implement A* Search for Optimal Vehicle Routing

Implement the A* search algorithm from scratch in Python (no use of library A* implementations). Use Euclidean distance as the admissible heuristic h(n). Apply it to find the shortest path in the traffic graph. Analyze time complexity, prove admissibility of your heuristic, and visualize the explored nodes vs. the optimal path.

Instructor Solution — Week 4 (A* from Scratch)

```
# Week 4: A* Search Implementation
# File: astar.py

import heapq
import math
from dataset_builder import TrafficNetworkDataset

class AStarSearch:
    def __init__(self, graph, positions):
        """
        graph: networkx DiGraph
        positions: dict {node_id: (lat, lon)}
        """
        self.graph = graph
        self.positions = positions
        self.explored = []   # for visualization

    def heuristic(self, u, goal):
        """
        Admissible heuristic: Euclidean distance (never overestimates).
        Proof: h(n) <= actual_cost because direct line < road path.
        Time complexity of heuristic: O(1)
        """
        lat1, lon1 = self.positions[u]
        lat2, lon2 = self.positions[goal]
        # Haversine formula for geographic distance
        R = 6371  # Earth radius in km
        dlat = math.radians(lat2 - lat1)
        dlon = math.radians(lon2 - lon1)
        a = (math.sin(dlat/2)**2 +
             math.cos(math.radians(lat1)) *
             math.cos(math.radians(lat2)) *
             math.sin(dlon/2)**2)
        dist_km = 2*R*math.asin(math.sqrt(a))
        # Convert km to minutes at 40 km/h average
        return (dist_km / 40) * 60
```

```
    def search(self, start, goal, weight='base_time'):
        """
        A* Search.
        Time Complexity: O((V + E) log V) using binary heap.
        Space Complexity: O(V)
        Returns: (path, cost, nodes_explored)
        """
        # Priority queue: (f_cost, node)

    print(f'Optimal path: {" -> ".join(names)}')
    print(f'Cost: {cost:.2f} min | Nodes explored: {explored}')
```

WEEK 5
WP1 + WP3

Multiple Models — Genetic Algorithm

Task 5 — Genetic Algorithm for Traffic Signal Optimization

Implement a full Genetic Algorithm to optimize signal timing across all intersections simultaneously. Chromosome representation: each gene = (green_time, red_time) for one intersection. Population size: 100. Selection: Tournament. Crossover: Two-point. Mutation: Gaussian perturbation. Termination: 200 generations or fitness plateau. Plot convergence curve.

Instructor Solution — Week 5 (Genetic Algorithm)

```
# Week 5: Genetic Algorithm for Signal Timing
# File: genetic_algorithm.py

import numpy as np
import random
import matplotlib.pyplot as plt

class TrafficGA:

WEEK 6
WP1 + WP3

Multiple Models / Approaches & Comparison

Task 6 — Comparative Algorithm Analysis

Implement and compare at least 6 algorithms on the same traffic routing problem: A* Search, Dijkstra, BFS, DFS, Greedy Best-First Search, and Random Search. For each algorithm record: solution quality (total path cost), execution time (ms), nodes explored, and memory usage. Present results in a structured table and statistical analysis (mean, std, t-test).

Instructor Solution — Week 6 (Comparison Framework)

Expected Results Table (sample output):

Algorithm	Path Cost (min)	Time (ms)	Nodes Explored	Optimality
A* Search	18.4	2.1	8	Optimal (admissible h)
Dijkstra	18.4	3.8	19	Optimal
BFS	24.7	1.9	15	Suboptimal (unweighted)
DFS	31.2	1.2	12	Suboptimal (incomplete)
Greedy Best-First	20.1	1.8	6	Suboptimal
Random Search	47.3	5.4	20	No guarantee

WEEK 7
WP3 + WP4

Presenting Improvement Upon Previous Work

Task 7 — Hybrid GA + A* System & Novel Contribution

Combine the GA signal optimizer with A* routing into a closed-loop system: GA optimizes signal timings, which updates edge weights, which then feeds A* with improved travel times. Demonstrate that the hybrid system achieves at least 15% lower average journey time than baseline static signals. Prove your contribution is novel and compare to the literature cited in Week 1.

Instructor Solution — Week 7 (Hybrid System)

```
# Week 7: Hybrid GA + A* Pipeline
# File: hybrid_system.py

from genetic_algorithm import TrafficGA
from astar import AStarSearch
from dataset_builder import TrafficNetworkDataset
import numpy as np

class HybridTrafficSystem:
```

```

    print('First application to Chittagong road network topology')
```

WEEK 8
WP1

ML Model for Congestion Prediction

Task 8 — Random Forest for Traffic Congestion Prediction

Train a Random Forest Regressor to predict congestion index from time features (hour, day, is_rush_hour, is_weekend). Compare with a Decision Tree baseline. Evaluate using RMSE, MAE, and R^2. Plot feature importance. Explain how this ML prediction feeds into the GA fitness function to make it adaptive rather than static.

Instructor Solution — Week 8

```
# Week 8: ML Model — Random Forest Congestion Predictor
# File: ml_model.py

from sklearn.ensemble import RandomForestRegressor
from sklearn.tree import DecisionTreeRegressor

```

WEEKS 9-10
All WPs

Final Project Showcase & Viva Preparation

Task 9-10 — System Integration, Demo & Viva

Integrate all modules into a single runnable system. Prepare a live demonstration showing: (1) the road network graph displayed with node names, (2) A* pathfinding animated on the graph, (3) GA convergence curve plotted, (4) hybrid system improvement quantified, (5) ML prediction error metrics displayed. Each team member must be able to explain every module independently during the viva.

Viva Question	Expected Answer Keywords
Why is A* optimal?	Admissible heuristic — never overestimates — guarantees shortest path by f(n)=g(n)+h(n)
Prove your GA converges	Schema theorem: short, low-order, above-average schemata grow exponentially — Holland 1975
What is WP1 and how did you satisfy it?	Advanced AI knowledge — GA mathematics, A* heuristic proof, graph complexity analysis
Time complexity of A* vs Dijkstra?	A*: O((V+E) log V) with heuristic pruning; Dijkstra: O((V+E) log V) no pruning — A* faster in practice
Why is this a WP4 problem?	No prior AI system for Chittagong road network — novel problem framing, original dataset, no published benchmark
How does GA fitness function work?	Webster delay formula — minimize sum of intersection delays — penalize infeasible signal timings
What is the research gap?	No hybrid GA+A* system applied to Bangladeshi urban road topology with real traffic density patterns

WEEKS 11-12
Documentation

Final Report & Presentation

Task 11-12 — Final Report Structure & Presentation Guidelines

Report Section	Required Content	Pages
Abstract	Problem, method, results in 250 words	0.5
Introduction	Motivation, Chittagong traffic problem, WP justification	2
Literature Review	8+ papers, gap analysis, comparison table	3
System Design	Architecture diagram, module descriptions, data flow	3
Dataset	Collection method, statistics, preprocessing decisions	2
Algorithm Implementation	A* with proofs, GA with math, code explained	5
Experiments & Results	Tables, graphs, statistical tests, comparison	4
Novel Contribution	How this improves on prior work, WP4 justification	2
Conclusion & Future Work	Findings, limitations, future directions	1.5
References	IEEE format, minimum 10 references	1

4. Marks Breakdown

The following table shows how all components of the lab project are graded. The total marks are distributed across weekly deliverables, the final showcase, viva, report, and presentation.

#	Component	WP Covered	Key Criteria
1	WP1 (Depth of Knowledge)	WP1	GA/A* mathematical correctness, complexity analysis
2	WP3 (Depth of Analysis)	WP3	Problem abstraction, NP-hard justification, Python quality
3	WP4 (Familiarity of Issues)	WP4	Novelty, original framing, research gap identified
4	Proposal & Literature Review	WP4	8+ papers, gap, measurable objectives
5	Dataset Preparation	WP1	Graph construction, data richness, schema design
6	Pre-processing Dataset	WP1	Cleaning, normalization, feature engineering, splits
7	Sample ML/AI Model	WP1	A* or baseline ML: correctness, testing, analysis
8	Multiple Models & Comparison	WP1+WP3	6+ algorithms, statistical analysis, fair comparison
9	Improvement Upon Prior Work	WP3+WP4	Hybrid system, >= 15% improvement, proof of novelty
10	Final Showcase	All	System demo, functionality, usefulness, UI/UX
11	Final Viva	All	Individual understanding, contribution clarity
12	Final Report	All	Documentation quality, technical depth, IEEE format
13	Final Presentation	All	Communication, visual clarity, Q&A handling
	TOTAL		

5. CEP Group Assignment Guidelines

5.1 How Groups Are Formed

Each group will consist of 3–4 students assigned by the instructor. Every group receives a unique CEP problem that shares the same algorithmic framework (GA + A* + ML) but differs in the

application domain. This ensures no two groups produce identical work and every student genuinely contributes.

Group	CEP Domain	GA Application	A* Application	Dataset Source
Group 1	Smart City Traffic (example above)	Signal timing optimization	Vehicle route planning	Synthetic Chittagong graph
Group 2	Hospital Resource Scheduling	Staff-shift assignment GA	Patient-ward path A*	Synthetic hospital floor plan
Group 3	Autonomous Drone Delivery	Delivery route GA	Obstacle-avoid A* in grid	Synthetic city grid
Group 4	Smart Energy Grid Load Balancing	Generator schedule GA	Power-flow A* on grid graph	IEEE 14-bus benchmark
Group 5	University Course Timetabling	Timetable GA	Room allocation A* search	IIUC course data
Group 6	Disaster Relief Logistics	Aid distribution GA	Evacuation route A*	Synthetic disaster map

Note: All groups must satisfy WP1, WP3, and WP4 through their domain. The algorithms must be implemented from scratch (no sklearn for A or GA). Groups are encouraged to extend the hybrid pipeline concept to their domain in a novel way.*

5.2 Academic Integrity

- All code must be written by the group members. Use of LLM-generated code without understanding is a violation.
- Each member will be individually viva-examined. Inability to explain any module results in zero marks for that component.
- Plagiarism detection will be applied to all reports using Turnitin.
- GitHub commit history will be reviewed to verify individual contributions.

Instructor Note

This document is provided as a complete reference solution to guide students through a genuine Complex Engineering Problem. Students are expected to understand every line of code and every mathematical justification. The goal is not to copy this solution but to internalize the engineering mindset it represents: rigorous problem formulation, principled algorithm selection, empirical evaluation, and original contribution. Good luck!

— Muhammad Mubinur Rahman, Instructor, CSE-3636, IIUC
